

- 1.) A type can be two things in programming which is a variable or a value. It can be defined as a variety of classifications that determine the possible values and the associated operations that can be used.
- 2.) The difference between strongly and weakly typed programming languages is the flexibility of types. In a strongly typed programming language a type is final and it cannot be used as if it were another type. In a weakly typed programming language a type can be easily manipulated and used as another type.
- 3.) Applications written in a strongly typed programming language usually have fewer bugs than a weakly typed programming language because it will prevent various errors especially type errors due to how it uses types.
